“Multimode Observation of Virus Capsid Assembly”

The Hepatitis B Virus (HBV) capsid protein self assembles and packages viral RNA while also serving as a compartment for DNA synthesis. Assembly and disassembly of the viral capsid have become targets for antiviral agents. The goal of this application is to develop methods for targeting cargo to a capsid by linking it to a small molecule that binds the capsid in high affinity and, as a result, using the capsid as a delivery device. Release of the cargo will be accomplished via chemical, redox, or light activated capsid disassembly providing the means for development of a programmable drug delivery system.

“Dynamics of Bacterial Peptidoglycan Biosynthesis”

The long-term goal of this application is to elucidate the mechanism(s) of peptidoglycan (PG) synthesis dynamics. This will be achieved through the development of improved fluorescent D-amino acids (FDAAAs) with improved photophysical properties and to use nanochannel and microfluidic devices to determine the dynamics of PG synthesis in ovoid and rod-shaped bacteria. At the conclusion of these studies, we will have synthesized a new set of fluorescent probes that will greatly facilitate the study of PG synthesis at high spatiotemporal resolution, we will have developed microfluidic devices with precise liquid handling that will enhance our ability to use the FDAA probes to study PG synthesis with cutting-edge microscopy in time-lapse and real time studies, and we will identify new genes that control the dynamics of PG synthesis.
